We examined the crystallization impact of the surfactant, 2-aminonicotinic acid and/or β -cyclodextrin on the formation of two anhydrous metal carbonates, MCO_3 ($M = Ca^{2+}$ and Sr^{2+}), from their respective calcium chloride and strontium chloride salts along with $NaHCO_3$ at room temperature. By varying the concentrations of this hybrid surfactant to the concentrations of MCO_3 during the preparations and examined their particle sizes by PXRD, FTIR, TGA and SEM. The characterization on these newly formed anhydrous metal carbonates clearly indicated that $CaCO_3$ formed with three different shapes such as truncated calcite, hexagonal calcite and rod shaped aragonite. Whereas, $SrCO_3$ formed with two different shapes such as hexagonal poles and bloom scale bars by varying concentrations of the surfactants. The mixed surfactant certainly made an impact on the metal carbonates formations with different shapes and sizes by varying surfactants concentrations and conditions.

Keywords: β -Cyclodextrin, Calcium carbonate, 2-Aminonicotinic acid, Strontium carbonate, Morphology.

INTRODUCTION

Nature utilizes many natural surfactants from plants and animals to control and direct the crystallization process during natural mineral formations. The natural and biological macromolecules could control the nucleation process during their formation to get various beautiful precious stones with amazing shapes and gem morphology. For example, natural network comprises of an auxiliary system of compromising hydrophobic macromolecules related to acidic macromolecules that go about as a nucleation surface for bio-mineralization. Later, these natural minerals give another course to integrate with various other minerals and materials to form a variety of new materials with desired properties and applications. In nature, the assortment of strong inorganic minerals and materials with intriguing properties and various leveled structures are solidified affected by natural surfactants [1]. Moreover, natural surfactants certainly impact the size, shape and morphologies of minerals and materials, which could certainly play a crucial

role in their physical, biological and mechanical properties of formed materials. In the literature, various studies were reported to investigate the impact of natural surfactants on the nucleation, development and morphology of inorganic materials [2-8].

Reused by the formation process of the biominerals utilizing natural layouts, along with new synthetic methodologies and processes achieved extraordinary materials in the field of biomimetic area of research and materials science [9-16] too. In fact, among the many important commonly used minerals, $CaCO_3$ is a seriously contemplated in light of its bounty as a biomineral in nature. Henceforth, for making a variety of morphologies of $CaCO_3$, various methodologies were tried including Langmuir monolayers [17], self-amassed monolayers [18], miscelles [19], microemulsions [20], etc. Moreover, as fluctuated dissolvable added substances such as manufactured peptides [21], dendrimers [22], microorganisms [23] and chiral compounds [24] have been studied to control polymorphs, directional conglomeration, size and shape control of $CaCO_3$ precious stones.

Abstract

A simple, selective, linear, precise and accurate UPLC method was developed and validated for rapid assay of Promethazine Theoclate in Bulk and Pharmaceutical tablet Formulation. The chromatographic analysis was performed on a Jasco Model: V-630, with a fixed bandwidth 2 nm and a pair of 1cm matched quartz cell at ambient temperature. The UV detection wavelength was observed at 252nm and injected sample is 20µl. Isocratic elution at a flow rate of 1.0ml/min was employed. The Mobile phase consisting of 0.05M KH₂PO₄ (to pH 3 with Phosphoric acid) 95V/V and Acetonitrile 5V/V Methanol and water in the ratios of 50v/v and 50v/v. The Rt for Etophyllin was ± 12 minutes approximately is identified. The Average percentage recovery of the method was in the range of 99-102%. The method was validated as per the ICH guidelines. The method was successfully applied for routine quality control analysis of pharmaceutical formulation.

In this paper, we have demonstrated the application of the U(2) Lie algebraic method to predict the vibrational frequencies of sulfur dioxide (SO₂). A Hamiltonian that preserves the C_{2v} point group symmetry of the molecule is devised using three interacting Morse oscillators. Root mean square deviation of the calculated vibrational frequencies is found to be 1.054 cm⁻¹ with reference to their experimental values. This asserts that the U(2) Lie algebraic method is successful in calculating the fundamental vibrational frequencies, and their higher overtones near to the spectroscopic level of accuracy.

topics: vibrational frequencies, sulfur dioxide, U(2) Lie algebraic method

1. Introduction

Theoretical calculations of vibrational frequencies of polyatomic molecules have been one of the interesting research areas for scientists on account of the development of innovative spectroscopic techniques. The investigation of vibrational spectra of molecules has been improved in recent years both theoretically and experimentally. Two approaches have been predominantly used so far in the study of experimental spectra: the well-known Dunham-like expansion of energy levels in terms of rotation-vibration quantum numbers and the solution of the Schrödinger equation with potential functions.

In this work, we applied the Lie algebraic method to study the vibrational frequencies of sulfur dioxide. This method reformulates the Hamiltonian operator in terms of elements of the Lie algebra and provides the same physical information as that of the Dunham and potential approaches [1, 2]. The advantage of the proposed method, as compared to that of the Dunham or potential approach, is that usually fewer parameters are required to get the same level of accuracy, in contrast to their comparators [3, 4]. The Lie algebraic method makes it possible to predict the vibrational frequencies much more accurately and possibly at a much lesser computational cost as compared to other theoretical

approaches. The lesser computational cost of the Lie algebraic framework is evident from the lesser demand of computational time for performing algebraic manipulations, rather than integration and differentiation of the potential function as in other approaches [1, 2].

2. The U(2) Lie algebraic method

Sulfur dioxide (SO₂) is a bent triatomic molecule with the equilibrium structure belonging to the C_{2v} point group symmetry. The molecule is non-linear with 3 vibrational degrees of freedom. Each of the vibrating bonds in SO₂ molecule is effectively described by a one-dimensional Morse oscillator and is assigned with a corresponding U(2) Lie algebra, as per the schematic shown in Fig. 1.

The two possible chains of dynamical symmetry groups in SO₂ molecule, corresponding to the local and normal couplings in stretching vibrations, are given by

$$U_1(2) \otimes U_2(2) \supset O_1(2) \otimes O_2(2) \rightarrow \text{local coupling} \quad (1)$$

$$U_1(2) \otimes U_2(2) \supset U_{12}(2) \supset O_{12}(2) \rightarrow \text{normal coupling} \quad (2)$$

The interaction results in three normal mode vibrations ν_1 , ν_2 , and ν_3 , correspond to the symmetry species A₁ (symmetric stretch), B₁ (asymmetric stretch), and A₁ (bend).

Physical growth of Natural Soils Contamination and their metamorphosis of Mineralogical soils in vermiculite

Abstract

This present work established the consequences of acidic and alkaline pore fluids over swell performance to inclusive soil. Observing the behaviour for transformations to various soils alkalis contaminate those is much needed to identify unique mineralogy and morphology variations. Authors are well concentrated on the effect of interactions of alkali over soils with increasing strength to a definite period along with an increase in interaction period to specified strength. A total of three different forces for sulphuric acid and potassium hydroxide were utilised as pore fluids for understanding the influence of variable strengths over the swell action of the soil. In contrast, their swelling decreased in the initial stage at a lower strength of sulphuric acid, later enhanced with an increase in solution strength. Two different vermiculite (magnesium-aluminium-iron silicate) soils were used as Diopside and tremolite. These are interacted by various strengths (0.5N, 0.1N, 2N, and 4N) of potassium hydroxide solutions within 9, 32, and 98 days. Complexity in swell variations in contaminated soil is identified accurately by investigating with the help of X-ray diffraction, SEM, and Energy dispersive analysis of X-ray at the end of an interaction. Artificially contaminated samples are subjected to research using various instruments and finally concluded with SEM to mineralogical and their diagnosis variations. Keywords: Vermiculite, Metamorphosis, SEM, Dispersive analysis of Energy.

Keywords: Vermiculite, Metamorphosis, SEM, Dispersive analysis of Energy.

INTRODUCTION

The spawning of different projects for industries and poor waste disposal practices is an excellent understanding of soil behaviour. This is changed latter extreme circumstances for the environment; even though pollutant of soil interaction alters fundamental properties of soil, swelling behaviour of soil, having the capability for causing damage to foundations and superstructures built over it. Valuable (Mal'tsev 1998) insight into the effects of infiltration of solutions like acids and alkalis of different strengths in beds of their structure production. In previous years, several researchers have reported various studies on the effect of acids and alkali over distended clayey soils (Assa'ad 1998, Chunikhin et al. 1988, Joshi et al. 1994). Different authors identified various essential factors, including the composition of chemical and strength of pore fluid, pH-medium, type and degree of electrolyte dissociation (Kabanov et al. 1977, Shekhtman et al. 1995, Sridharan et al. 1981) chemico-mineralogical composition, and exchange capacity (Rao et al. 1994), etc.; Studies disclosed that even soil fabric and its structure significantly influences geotechnical properties whenever interacting by different contaminants under disparate strengths (James et al. 1981, Mitchell et al. 2005). Additional case studies are more related to soil contamination; alkali to crack causes failure to foundation soils and superstructures (Rao et al. 1994, Sinha et al. 2003), as impacts are asymptomatic. The behaviour of stable minerals is affected by contamination by alkali (Turer 2005, Sivapullaiah et al. 2005). Various literature on mineral types present in soil under alkali circumstances can attribute different phases in mineral transformations to various temperature circumstances. Anyhow, out of multiple available soils, Red natural earth and commercial china clay are studied in this work. Interaction of (De la Villa et al. 2005) montmorillonite by alkali solutions among pH 10.3.5 denoted in zeolites formation. Various researchers' information revealed that the association of smectite by Ca(OH)₂, NaOH, and KOH solutions altered fraction by the construction of interstratified illite smectite, a crystalline form of alkali alumina silicates.
